

Radioactive contaminants in decommissioned nuclear steam generators

Here is a partial list of radioactive contaminants inside a used steam generator from one of the Bruce reactors. The amount of radioactivity is expressed in becquerels per cubic metre; one becquerel corresponds to one radioactive disintegration every second. (Source: OPG)

TOTALS					
Long half-lives only		8.7E+09	(long-lived)		8 700 000 000
Including short half-lives		1.6E+10	(all radionuclides)		16 000 000 000

According to this OPG document (last 2 lines), in each cubic metre there are over eight BILLION radioactive disintegrations taking place every second. Each disintegration releases an alpha ray, a beta ray, or a gamma ray; so there are more than eight billion of these rays emitted every second. That's more than 28 trillion rays per hour – over 245 quintillion (245 000 000 000 000 000) rays per year!

As one striking example: there are five plutonium isotopes found in the steam generators. In each cubic metre there are about 580 million alpha rays given off each second just from these plutonium isotopes alone. One thousand years in the future, if the steam generators were just stored on-site as radioactive waste for that entire period, these plutonium isotopes would still be giving off about 30 million alpha particles per second, per cubic metre.
